

Beginner Python Notes

A loop repeats a step. A **for loop** is useful when you want to visit each value in a group.

Example

```
for score in scores:  
    print(score)
```

What this means:

- **scores** is the whole list
- **score** is one value from the list
- the loop runs once for each value
- **print(score)** shows one score at a time

Another example

```
numbers = [3, 5, 8]  
  
for item in numbers:  
    print(item)
```

This means:

- the program goes through **numbers** one item at a time
- **item** becomes 3, then 5, then 8
- the loop variable only holds one value on each turn

Simple explanation: A for loop is like checking each card in a stack one by one.
